Abstract: The present study was conducted on skin samples of 4 – 6 years of age healthy Deoni, Red kandhari, Dangi and Gaolao breeds of cattle managed under hygienic conditions on farm in different regions of Maharashtra. The skin samples, 10 of each breed were obtained surgically from loin region during winter and summer seasons separately. The average thickness of skin recorded immediately after collection was found maximum during winter season in all cattle breeds.

Keywords: Skin, thickness, cattle.

Material and Methods

The present study was conducted in the Department of Veterinary Anatomy and Histology, College of Veterinary and Animal Sciences, Parbhani (M.S.). The experiment was carried out on 40 female cattle of 4 – 6 years of age belonging to different breeds located in different regions of Maharashtra state during winter (November - February) and summer (March – June) seasons, separately. The skin samples, 10 of each were obtained from loin region of healthy Deoni, Red kandhari, Gaolao and Dangi breeds of cattle, managed under hygienic conditions on the farm in different regions of Maharashtra state.

The skin samples were obtained by performing following surgical operative technique:

Operative technique

The area of loin region irrespective of side between 2nd and 3rd lumbar transverse process was cleaned, shaved and disinfected with spirit. An elliptical skin sample of 1 cm length along with fascia was taken out surgically after infiltration of local analgesia. The antiseptic powder was sprinkled on the surgical wound and the incised wound was sutured by interrupted suture using nylon thread. The wound was sealed with tincture iodine.

The obtained skin samples were washed immediately with normal saline solution to remove blood clots. The thicknesses of the skin were recorded gently with the help of *Oxytetracycline – Indian Immunologicals, Hyderabad digital vernier callipers immediately.
Results and Discussion

Thickness of skin

The total thickness of fresh skin snippets included of epidermis, dermis and hypodermis was measured immediately after collection of skin samples using digital Vernier callipers.

The average thickness of fresh skin snippets in summer was 5.03 ± 0.08 mm, 4.11 ± 0.06 mm, 4.79 ± 0.05 mm and 4.95 ± 0.07 mm whereas, during winter it was recorded as 5.41 ± 0.20 mm, 4.71 ± 0.10 mm, 5.31 ± 0.05 mm and 5.20 ± 0.04 mm in Deoni, Red Kandhari, Dangi and Gaolao breeds of cattle respectively (Table 1).

In the present investigation, the total thickness of skin in Deoni and red Kandhari cattle was within the range reported by Mugale (2000) in Deoni and Hole (2003) in Red Kandhari cattle. Also, total skin thickness of Gaolao and Dangi cattle were within the range of other indigenous breeds of cattle as reported by Bhayani et al. (1989) at mid side region in Kankrej cow, Bhayani and Vyas (1990) in Gir cattle, Hamid et al. (2000) in skin of hind quarter in indigenous X Sahiwal cattle and Aslan et al. (2004) in Zavot cattle. However, the average thickness of skin recorded in all breeds of cattle in present study was found lower than the skin thickness reported by Nay and Hayman (1963) in European breeds of cattle, Hayman et.al (1966) in Sahiwal cattle, Dowling (1955) in Zebu and European breeds of cattle, Walker (1963) in Indigenous breeds of African cattle, Mohan and Prabhu (1969) skin of back region in Hariana and Tharparkar cattle and Dowling (1964) in different Breeds of European cattle. This Variation in skin thickness may be due to age, site, climatic conditions and breed differences. Similarly, Patel et al. (1988), Bhayani and Vyas (1990), Fazzini and Peirone (1985) and Saxena et al. (1994) mentioned significant variation in skin thickness as per age. Aslan et al. (2004), Hamid et al. (2000), Mohan and Prabhu (1969) and Bhatia and Prabhu (1970) reported variation in skin thickness from site to site. Also, Nay and Hayman (1963), Hayman et al. (1966) and Dowling (1964) reported breed and seasonal effect on the variation of skin thickness.

The increase in thickness of skin during winter season might be attributed to protection of animals from extreme cold. Similar observations were reported by Nay and Hayman (1963). They recorded more thickness of skin in winter than summer season in different breeds of European cattle.
The average thickness of skin showed statistical significant variations between breeds in both season during present work. However, non-significant difference was observed between Deoni and Gaolao cattle during summer season and between Deoni and Dangi cattle during winter season. The maximum thickness of skin in present study was recorded in Deoni cattle and minimum in Red Kandhari cattle during both seasons.
